# 1 Introduction

This report investigates three different approaches to matrix multiplication. In Problem A-1, we explore the conventional matrix multiplication algorithm and do it in six different ways to interchange the loops to optimize its performance. In Problem B-1, we study the use of transpose matrix multiplication as a way to reduce the computational cost of matrix multiplication. Finally, in Problem C-1, we analyze the block matrix multiplication algorithm, which uses a divide and conquer strategy to compute the product of two large matrices. For each problem, we provide a detailed analysis of the algorithms, including their computational complexity. We also implement each algorithm and evaluate its performance on matrices of different sizes. The results of our experiments are presented in the form of graphs.

## 2 Hardware Details

### 2.1 Lab 207 PC

- Architecture: x86\_64
- CPU op-mode(s): 32-bit, 64-bit
- Byte Order: Little Endian
- CPU(s): 4
- On-line CPU(s) list: 0-3
- Thread(s) per core: 1
- Core(s) per socket: 4
- Socket(s): 1
- NUMA node(s): 1
- Vendor ID: GenuineIntel
- CPU family: 6
- Model: 60
- Model name: Intel(R) Core(TM) i5-4590 CPU @ 3.30GHz
- Stepping: 3
- CPU MHz: 3300.000
- CPU max MHz: 3700.0000
- CPU min MHz: 800.0000
- BogoMIPS: 6585.38

- Virtualization: VT-x
- L1d cache: 32K
- L1i cache: 32K
- L2 cache: 256K
- L3 cache: 6144K
- NUMA node0 CPU(s): 0-3

## 2.2 HPC Cluster

- Architecture: x86\_64
- CPU op-mode(s): 32-bit, 64-bit
- Byte Order: Little Endian
- CPU(s): 16
- On-line CPU(s) list: 0-15

- Thread(s) per core: 1
- Core(s) per socket: 8
- Socket(s): 2
- NUMA node(s): 2
- Vendor ID: GenuineIntel
- CPU family: 6
- Model: 63
- Model name: Intel(R) Xeon(R) CPU E5-2640 v3 @ 2.60GHz
- Stepping: 2
- CPU MHz: 1976.914
- BogoMIPS: 5205.04
- Virtualization: VT-x
- L1d cache: 32K
- L1i cache: 32K
- L2 cache: 256K
- L3 cache: 20480K
- NUMA node0 CPU(s): 0-7
- NUMA node1 CPU(s): 8-15

### 3 Problem C1

#### 3.1 Description of the problem

Given two square matrices  $A$  and  $B$  of size  $n \times n$ , we want to compute their product  $C = AB$ . We can use a block matrix multiplication algorithm that partitions both matrices into smaller submatrices of size  $block\_size \times block\_size$  and applies certain rules to obtain each submatrix in  $C$ .

Let us denote the submatrices of  $A$ ,  $B$  and  $C$  as follows:

$$A = \left[ \begin{array}{c|c} A_{11} & A_{12} \\ \hline A_{21} & A_{22} \end{array} \right], B = \left[ \begin{array}{c|c} B_{11} & B_{12} \\ \hline B_{21} & B_{22} \end{array} \right], C = \left[ \begin{array}{c|c} C_{11} & C_{12} \\ \hline C_{21} & C_{22} \end{array} \right].$$

where each submatrix has size  $block\_size \times block\_size$ . Then we can apply the following rule to obtain each submatrix in  $C$ :

$$C = AB = \left[ \begin{array}{c|c} A_{11}B_{11} + A_{12}B_{21} & A_{11}B_{12} + A_{12}B_{22} \\ \hline A_{21}B_{11} + A_{22}B_{21} & A_{21}B_{12} + A_{22}B_{22} \end{array} \right].$$

The block matrix multiplication algorithm computes each submatrix product and sum by iterating over all possible combinations of blocks in  $A$ ,  $B$  and  $C$ . The algorithm assumes that  $n$  is divisible by  $block\_size$ . Otherwise, some elements may be left out or accessed out of bounds.

#### 3.2 Serial Complexity

This method requires same number of operations as the standard matrix multiplication algorithm, i.e.,  $O(n^3)$ .

#### 3.3 Profiling Information

Following are the snapshots taken while profiling.

```

Flat profile:

Each sample counts as 0.01 seconds.
%   cumulative   self           self       total
time  seconds    seconds   calls   Ts/call  Ts/call  name
100.88      5.25      5.25         1      5.25     5.25  block_matmul

%           the percentage of the total running time of the
time        program used by this function.

cumulative  a running sum of the number of seconds accounted
seconds     for by this function and those listed above it.

self        the number of seconds accounted for by this
seconds     function alone. This is the major sort for this
            listing.

calls       the number of times this function was invoked, if
            this function is profiled, else blank.

self        the average number of milliseconds spent in this
ms/call     function per call, if this function is profiled,
            else blank.

total       the average number of milliseconds spent in this
ms/call     function and its descendents per call, if this
            function is profiled, else blank.

name        the name of the function. This is the minor sort
            for this listing. The index shows the location of
            the function in the gprof listing. If the index is
            in parenthesis it shows where it would appear in
            the gprof listing if it were to be printed.

### 3.4 Optimization Strategy

I chose 32 as the block size for block matrix multiplication because it is close to the upper bound given by the formula:

$$block - size \leq \sqrt{\frac{L1_{cache-size}}{3 * word - size}} \quad (1)$$

where  $L1_{cache-size}$  is the size of my L1 cache in bytes and  $word - size$  is the size of my data type in bytes. The formula is based on the assumption that my L1 cache can store 3 blocks (block-size \* block-size) of data at a time, one for each matrix involved in the multiplication. This way, I can minimize the number of cache misses and improve the computational efficiency of the operation.

Since I have a 32 KB L1 cache and a double data type (which has 8 bytes), I can calculate:

$$block - size \leq \sqrt{\frac{32 * 1024}{3 * 8}} \approx 36 \quad (2)$$

This means that the optimal block size should be less than or equal to 36 for optimal performance. I chose 32 because it is a power of two and it can fit well into the cache memory without wasting any space. Powers of two are often preferred for block sizes. I also tested different block sizes ranging from 4 to 64 and measured their execution time. I found that 32 gave me the fastest execution time among all the tested values.

Therefore, based on theoretical analysis and empirical testing, I concluded that 32 is a good choice for the block size for block matrix multiplication.

### 3.5 Graph of Problem Size vs Algorithm Runtime

### 3.6 Discussion

Conventional matrix multiplication does not use any partitioning and multiplies each element of one matrix with each element of another matrix. It has a time complexity of  $O(n^3)$  for multiplying two  $n \times n$  matrices.

Block matrix multiplication uses a partitioning scheme that divides the matrices into smaller submatrices or blocks, and then multiplies them using standard matrix multiplication. It has a time complexity of  $O(n^3)$  for multiplying two  $n \times n$  matrices, but it can be faster than conventional matrix multiplication due to better cache utilization.

The advantage of block matrix multiplication is that it reduces the number of cache misses by reusing the data in each block as much as possible. The optimal block size depends on the size of the matrices and the cache parameters. The disadvantage of block matrix multiplication is that it requires additional memory allocation and copying for storing and accessing the blocks.

In conclusion, block matrix multiplication and conventional matrix multiplication are two equivalent methods for computing the product of two matrices, but they have different trade-offs in terms of performance and memory usage. Block matrix multiplication can be faster than conventional matrix multiplication by exploiting spatial and temporal locality of data, but it requires more memory management and careful partitioning.
